

Problem 1. Consider two speakers emitting sound at the same volume with frequency $f = 800 \text{ Hz}$. One speaker is located at the origin, and the other on the y axis at $y = 2 \text{ m}$. At what locations on the positive x axis is the interference completely constructive? At what points is it completely destructive?

Now we decrease f until there are no longer any points of completely destructive interference on the positive x axis. How low must f be for this to occur?

Solution. Consider the setup shown below:

The path difference d (which is called Δx in the lecture slides) is given by

$$d = d_B - d_A = d_A - x,$$

and from trigonometry,

$$d_B^2 = x^2 + (\Delta y)^2 \quad \implies \quad d_B = \sqrt{x^2 + (\Delta y)^2},$$

where Δy is the distance between the two speakers. Putting these together, we can write

$$d = \sqrt{x^2 + (\Delta y)^2} - x.$$

Completely constructive interference occurs where the interference pattern of the speakers has a maximum, which is when

$$d = n\lambda, \quad n = 0, \pm 1, \pm 2, \dots$$

Completely destructive interference occurs where it has a minimum, and

$$d = \left(n + \frac{1}{2}\right)\lambda, \quad n = 0, \pm 1, \pm 2, \dots$$

Recall that the wavelength $\lambda = v/f$, where $v = 344 \text{ m s}^{-1}$ is the speed of sound in air. For this problem,

$$\lambda = \frac{344 \text{ m s}^{-1}}{800 \text{ Hz}} = 0.43 \text{ m}.$$

Constructive interference will occur at x when

$$n\lambda = \sqrt{x^2 + (\Delta y)^2} - x.$$

Solving for x ,

$$(x + n\lambda)^2 = x^2 + (\Delta y)^2 \quad \implies \quad x^2 + n\lambda x + n^2\lambda^2 = x^2 + (\Delta y)^2 \quad \implies \quad n\lambda x = (\Delta y)^2 - n^2\lambda^2,$$

which implies

$$x = \frac{(\Delta y)^2}{n\lambda} - n\lambda. \quad (1)$$

Now we can plug in numerical quantities and $n = 0, \pm 1, \pm 2, \dots$ into Eq. (1) to find

$$\begin{aligned} x(n=1) &= \frac{(2\text{ m})^2}{0.43\text{ m}} - (0.43\text{ m}) = 8.87\text{ m}, \\ x(n=2) &= \frac{(2\text{ m})^2}{2(0.43\text{ m})} - 2(0.43\text{ m}) = 3.79\text{ m}, \\ x(n=3) &= \frac{(2\text{ m})^2}{3(0.43\text{ m})} - 3(0.43\text{ m}) = 1.81\text{ m}, \\ x(n=4) &= \frac{(2\text{ m})^2}{4(0.43\text{ m})} - 4(0.43\text{ m}) = 0.61\text{ m}. \end{aligned}$$

Note that x is undefined for $n = 0$ and is negative for $n > 4$. Plugging in $n = -1, -2, -3, \dots$ would also give us negative values. None of these makes sense since we are interested only in the positive x axis.

For destructive interference, we have to satisfy

$$\left(n + \frac{1}{2}\lambda\right) = \sqrt{x^2 + (\Delta y)^2} - x,$$

and solving for x in the same manner as before gives us

$$x = \frac{(\Delta y)^2}{(n + 1/2)\lambda} - \left(n + \frac{1}{2}\right)\lambda. \quad (2)$$

Plugging in numerical quantities and $n = 0, 1, 2, \dots$ into Eq. (2),

$$\begin{aligned} x(n=0) &= \frac{(2\text{ m})^2}{(1/2)(0.43\text{ m})} - \frac{1}{2}(0.43\text{ m}) = 18.4\text{ m}, \\ x(n=1) &= \frac{(2\text{ m})^2}{(3/2)(0.43\text{ m})} - \frac{3}{2}(0.43\text{ m}) = 5.56\text{ m}, \\ x(n=2) &= \frac{(2\text{ m})^2}{(5/2)(0.43\text{ m})} - \frac{5}{2}(0.43\text{ m}) = 2.65\text{ m}, \\ x(n=3) &= \frac{(2\text{ m})^2}{(7/2)(0.43\text{ m})} - \frac{7}{2}(0.43\text{ m}) = 1.15\text{ m}, \\ x(n=4) &= \frac{(2\text{ m})^2}{(9/2)(0.43\text{ m})} - \frac{9}{2}(0.43\text{ m}) = 0.13\text{ m}. \end{aligned}$$

Again, $x < 0$ for $n < 0$ and $n > 4$, which are not sensible.

In order to find the frequency for which there is no destructive interference on the x axis, we should look at $n = 0$, since this gives us the point with the largest value of x . If we plug $n = 0$ into Eq. (2) and set $x = 0$, we are requiring that destructive interference can only occur at the origin. Solving for the wavelength λ tells us the smallest wavelength at which there is still destructive interference. We find

$$0 = \frac{(\Delta y)^2}{\lambda/2} - \frac{\lambda}{2} \implies \frac{\lambda}{2} = \frac{(\Delta y)^2}{\lambda/2} \implies \frac{\lambda^2}{4} = (\Delta y)^2 \implies \lambda = 2\Delta y.$$

But if $\lambda > 2\Delta y$, then

$$\frac{(\Delta y)^2}{\lambda/2} < \frac{1}{2}\lambda,$$

and Eq. (2) tells us

$$x = \frac{(\Delta y)^2}{\lambda/2} - \frac{1}{2}\lambda < 0.$$

This means there is no destructive interference on the x axis. Thus, we need to satisfy

$$\lambda = \frac{v}{f} > 2\Delta y \quad \implies \quad f < \frac{v}{2\Delta y}.$$

Plugging in numbers, we find

$$f < \frac{344 \text{ m s}^{-1}}{2(2 \text{ m})} = 86 \text{ Hz}.$$
